

ABSTRACT OF THE DISCLOSURE

[0091] A method and apparatus for data communications over a wireless network. A user contacts an Internet gateway over the wireless network. When the user requests an Internet resource it sends an improved HTTP command to the gateway. The improved HTTP command causes the internet gateway to access a resource file and obtain not only the requested resource, but also all of the resources embedded in the requested resource. The requested resource and embedded resources are bundled into a file and sent to the user. By eliminating parsing of the requested resource by the user and subsequent requests for embedded information, the wireless network does not have to make multiple supplemental communication channel assignments, which improves overall performance.
